

# A GROUP DEFINABLE IN AN O-MINIMAL STRUCTURE WHICH IS NOT AFFINE

PANTELIS E. ELEFThERIOU

ABSTRACT. In this short note we provide an example of a group  $G$  definable in an o-minimal structure  $\mathcal{M}$  which does not admit an affine embedding; in other words, there is no definable isomorphism between topological groups  $f : G \rightarrow G' \subseteq M^m$ , such that the group topology on  $G'$  coincides with the subspace topology induced by  $M^m$ .

Let  $\mathcal{M}$  be an o-minimal structure. By “definable” we mean “definable in  $\mathcal{M}$ ” possibly with parameters. A group  $G = \langle G, \oplus, e_G \rangle$  is said to be definable if both its domain and the graph of its group operation are definable subsets of  $M^n$  and  $M^{3n}$ , for some  $n$ , respectively.

By [Pi], we know that every definable group  $G \subseteq M^n$  can be equipped with a unique definable manifold topology that makes it into a topological group. We refer to this topology as the *group topology of  $G$* . It is shown in [Pi] that the group topology of  $G$  coincides with the subspace topology induced by  $M^n$  on a large subset  $V$  of  $G$  ( $\dim(G \setminus V) < \dim(G)$ ). We call  $G$  *affine* if the group topology of  $G$  coincides with the subspace topology on (the whole of)  $G$ .

**Question.** *Is every definable group affine (up to definable isomorphism)?*

*Remark 0.1.* (i) A definable isomorphism between two definable groups is a group isomorphism as well as a topological homeomorphism with respect to their group topologies.

(ii) By [ElSt, Remark 2.2], the Question can be restated as follows: *Given a definable group  $G \subseteq M^n$ , is there a definable injective map  $\tau : G \rightarrow M^m$ ,  $m \in \mathbb{N}$ , such that the topology on  $\tau(G)$  induced by the group topology of  $G$  via  $\tau$  coincides with the subspace topology on  $\tau(G)$  induced by  $M^m$ ? If yes, then such a  $\tau$  is called an *affine embedding of  $G$* .*

The Question admits an affirmative answer in case  $\mathcal{M}$  expands a real closed field, by [BO, Proof of Lemma 10.4] and [vdD, Chapter 10, Theorem (1.8)]. In fact, the above references concern affine embeddings of “abstract definable-manifolds”, and the work in [BO] also yields affine embeddings which are moreover diffeomorphisms. The original proof of embedding semi-algebraic manifolds was given in [Ro].

We present here an example of a group definable in a linear o-minimal structure which is not affine. Linear o-minimal structures were studied in [LP], and groups definable in them were studied in [ElSt] and [El]. The main example of a linear

o-minimal structure is that of an ordered vector space  $\mathcal{M} = \langle M, +, <, 0, \{d\}_{d \in D} \rangle$  over an ordered division ring  $D$ . The main property of such an  $\mathcal{M}$  that we use below is that every definable function  $f : A \subseteq M^n \rightarrow M^m$  is piecewise linear, that is, there is a partition of  $A$  into finitely many definable sets  $A_i$ ,  $i = 1, \dots, k$ , such that for each  $i = 1, \dots, k$ , the following holds: there is an  $n \times m$  matrix  $\lambda$  with entries from  $D$ , and an element  $a \in M^m$ , such that for every  $x \in A_i$ ,  $f(x) = \lambda x + a$ .

For  $x, y \in M$ , we define:

$$x \prec_D y \Leftrightarrow \forall d \in D, dx < y.$$

**Example 0.2.** Let  $\mathcal{M} = \langle M, +, <, 0, \{d\}_{d \in D} \rangle$  be an ordered vector space over an ordered division ring  $D$  with the following property: there are  $a, b, c > 0$  in  $M$  such that  $b \prec_D c \prec_D a$ . In particular, there is no definable function from  $[0, b)$  onto  $[0, c)$ , and  $\forall n \in \mathbb{N}, nc < a$ .

Let  $S = [0, a) \times [0, b)$  and  $L = \mathbb{Z}(a, 0) + \mathbb{Z}(a - c, b)$  be the lattice in  $M^2$  generated by the elements  $(a, 0)$  and  $(a - c, b)$ . Define  $G = \langle S, \oplus, 0 \rangle$ , where

$$x \oplus y = z \Leftrightarrow x + y - z \in L.$$

By [ElSt, Claim 2.7(ii)],  $G$  is definable.

**Notation.** By  $\lim^G$  we denote a limit with respect to the group topology of  $G$ . A path is always a continuous map, and a  $G$ -path is a path which is continuous with respect to the group topology of  $G$ .

**Claim.** *There is no definable injective map  $\tau : G \rightarrow M^m$ ,  $m \in \mathbb{N}$ , such that the induced topology on  $\tau(G)$  coincides with the subspace topology.*

*Proof.* Assume, towards a contradiction, that there is such a  $\tau$ . For every element  $t \in [0, a)$ , consider the one-to-one  $G$ -path

$$\phi_t : [0, b) \rightarrow \{t\} \times [0, b), \text{ with } \phi_t(x) = (t, x).$$

By definition of  $G$ , we see that for every  $t \in [0, a - c]$ ,  $\lim_{x \rightarrow b}^G \phi_t(x) = (t + c, 0)$ . Therefore, for every  $t \in [0, a - c]$ ,  $\tau(\phi_t)$  is a path in  $M^m$  with the property:

$$\lim_{x \rightarrow b} \tau(\phi_t(x)) = \tau((t + c, 0)).$$

Consider now the image  $\tau([0, a - c] \times \{0\})$ . It contains an infinite number of elements of the form  $\tau((nc, 0))$ ,  $n \in \mathbb{N}$ . Since  $\tau$  is piecewise linear, there must exist some  $n \in \mathbb{N}$  such that  $\tau$  is linear on  $[nc, (n + 1)c) \times \{0\}$ . Hence the image  $\tau([nc, (n + 1)c) \times \{0\})$  is in bijection with an interval  $J \subseteq M$  via some projection onto one of the  $m$  coordinates. Since  $\tau(\phi_{nc}) : [0, b) \rightarrow M^m$  is a path with

$$\tau(\phi_{nc}(0)) = \tau((nc, 0)) \text{ and } \lim_{x \rightarrow b} \tau(\phi_{nc}(x)) = \tau(((n + 1)c, 0)),$$

it is easy to see that there is a definable map from  $\tau(\phi_{nc}([0, b)))$  onto  $J$ , and, therefore, there is a definable map from  $[0, b)$  onto  $J$ . It follows that there is a definable map from  $[0, b)$  onto  $[nc, (n + 1)c)$ , a contradiction.  $\square$
